

AI Assisted Coding

Assignment Number:1.3

Name:MD.ADIL

HtNo:2303A51988

BtNo:05

Lab 1: Environment Setup – GitHub Copilot and VS Code Integration + Understanding AI-assisted Coding Workflow

Task 0:

- Install and configure GitHub Copilot in VS Code. Take screenshots of each step.

Task 1: AI-Generated Logic Without Modularization (Fibonacci Sequence Without Functions)

Step-1:prompt

Create a simple python program that prints the Fibonacci series up to n terms. Do not use any functions. Take n as input from the user using Scanner and print the Fibonacci numbers in one single line with spaces between them.

A screenshot of the GitHub Copilot AI interface. The top navigation bar shows 'CHAT' and 'GITHUB'. Below the bar, a card displays the task prompt: 'Create a simple python program that prints the Fibonacci series up to n terms. Do not use any functions. Take n as input from the user using Scanner and print the Fibonacci numbers in one single line with spaces between them.' A file named 'fibnocciseries.py' is shown with lines 6-19 highlighted. Below the file content, a 'Step-by-step:' section lists three steps: 1. Read integer n from standard input and validate. 2. Handle n <= 0 (exit) and n == 1 (print 0). 3. Generate Fibonacci terms iteratively and print them on one line separated by spaces. The code editor shows the file 'fibnocciseries.py' with the following content:

```
fibnocciseries.py
Replace file content with:
✓ Edited [fibnocciseries.py +2 -2]
C ↻ ⌂ ⌂ ⌂
fibnocciseries.py
Edit or refactor selected code
Edit Auto
```

The status bar at the bottom right indicates 'GPT-5 mini • 1x'.

Step-2:Code

```
fibnocciseries.py > ...
try:
    n = int(input().strip())
except:
    # invalid input -> exit without output
    exit()
if n <= 0:
    exit()
if n == 1:
    print(0)
else:
    a, b = 0, 1
    out = [str(a), str(b)]
    for _ in range(n - 2):
        c = a + b
        out.append(str(c))
        a, b = b, c
    print(" ".join(out))

7
0 1 1 2 3 5 8
PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING> []

Step-by-step solution:
1. Read integer n from user with Scanner in main.
2. Handle n <= 0 (exit), n == 1 (print 0).
3. Iteratively generate Fibonacci terms in a loop (no functions) and print them on one line separated by spaces.

c:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING\fibnocciseries.py

Replace the file with a Java program that reads n and prints the first n Fibonacci numbers in one line separated by spaces.

fibnocciseries.py-19
Edit or refactor selected code
```

Step-4:Explanation

1. The program takes n as input using Scanner.
2. Two variables a = 0 and b = 1 store the first two Fibonacci numbers.
3. It prints a first because Fibonacci always starts with 0.
4. A loop runs from 1 to n-1 to generate the remaining terms.
5. In each loop, next = a + b calculates the new number.
6. The program prints b and then next in the next iterations.
7. After printing, it updates a = b and b = next for the next calculation.
8. Finally, the Fibonacci series prints in one single line with spaces.

Task 2: AI Code Optimization & Cleanup (Improving Efficiency)

Step-1:Prompt

Create a simple python program that prints the Fibonacci series up to n terms with using functions. Take n as input from the user using Scanner and print the Fibonacci numbers in one single line with spaces between them.

The screenshot shows a dark-themed AI-assisted coding interface. At the top, there's a header bar with tabs for 'CHAT' and 'GITHUB'. Below the header, a title bar says 'FIBONACCI SERIES PROGRAM WITHOUT FUNCTIONS'. A main text area contains the following prompt:

```
Write an efficient and optimized Python program that prints the Fibonacci series up to n terms.  
Take n as input from the user.  
Use variables smartly, remove unnecessary operations, keep the code clean and easy to read, and print the  
Fibonacci numbers in one single line separated by spaces.  
Make sure it runs fast even for large values of n.
```

Below the prompt, a 'Step-by-step:' section lists four steps:

1. Read and validate integer n from stdin.
2. Handle n <= 0 and n == 1/2 as special cases.
3. Iterate once ($O(n)$) computing next Fibonacci with a,b = b, a+b and stream output to stdout to avoid building large lists.
4. Use local variable bindings for speed and end with a newline.

The code editor window shows a file named 'fibnocciseries.py' with the following content:

```
fibnocciseries.py
Summary: Replace current implementation with a memory-efficient streaming version that avoids building lists and uses fast I/O.

```

Step-2:code

```
fibnocciseries.py > ...
1 import sys
2
3 try:
4     n = int(sys.stdin.readline().strip())
5 except:
6     exit()
7
8 if n <= 0:
9     exit()
10
11 a, b = 0, 1
12 write = sys.stdout.write
13
14 if n == 1:
15     write("0\n")
16 else:
17     write("0 1")
18     for _ in range(n - 2):
19         a, b = b, a + b
20         write(" " + str(b))
21     write("\n")
22
```

Step-3:Output

10
0 1 1 2 3 5 8 13 21 34
```

Step-4:Explanation

1. The program reads the number n from the user.
2. It sets two variables to start the sequence: a = 0 and b = 1.
3. A loop runs n times to generate Fibonacci numbers one by one.
4. In every iteration, it prints the current value of a.
5. The next number is calculated efficiently by swapping values instead of extra temp variables.
6. b always becomes the sum of the previous two numbers.
7. No function calls are used, so the program runs faster and stays simple.
8. The final output prints all Fibonacci numbers in one line with spaces, even for large n.

Task 3: Modular Design Using AI Assistance (Fibonacci Using Functions)

Step-1:prompt

Write a modular Python program that generates the Fibonacci series up to n terms using functions. Take n as input from the user. Use a separate function to compute the Fibonacci sequence efficiently and return the result. Print the output in one line with spaces between the numbers.

The screenshot shows a VS Code interface with the 'AI ASSISTED CODING' extension active. The 'fibnocciseries.py' file is open, and the code is as follows:

```
fibonacci.py fibnocciseries.py Extension: GitHub Copilot Chat
fibnocciseries.py > ...

try:
    n = int(input("Enter the number of terms: ").strip())
except:

    Write a modular Python program that generates the Fibonacci series up to n terms using functions. Take n as input from the user. Use a separate function to compute the Fibonacci sequence efficiently and return the result. Print the output in one line with spaces between the numbers.

    GPT-4.1

exit()

if n <= 0:
    exit()

5 | exit()

6 |
7 if n <= 0:
8     exit()

9 |
```

Step-2:Code

The screenshot shows the completed modular Fibonacci program in VS Code. The code is now well-structured with separate functions for input, computation, and output.

```
Fibonacci.py fibnocciseries.py Extension: GitHub Copilot Chat
fibnocciseries.py > ...

1 | def get_input():
2 |     try:
3 |         n = int(input("Enter the number of terms: ").strip())
4 |         if n <= 0:
5 |             return None
6 |         return n
7 |     except:
8 |         return None
9 |
10 def fibonacci_series(n):
11     if n == 1:
12         return [0]
13     seq = [0, 1]
14     for _ in range(n - 2):
15         seq.append(seq[-1] + seq[-2])
16     return seq
17 |
18 def main():
19     n = get_input()
20     if n is None:
21         return
22     series = fibonacci_series(n)
23     print(' '.join(map(str, series)))
24 |
25 if __name__ == "__main__":
26     main()
```

Step-03:Output

The screenshot shows the terminal output in VS Code, demonstrating the execution of the program and its modular structure.

```
Fibonacci.py fibnocciseries.py Extension: GitHub Copilot Chat
fibnocciseries.py > ...

1 |
2 | def get_input():
3 |     try:
4 |         n = int(input("Enter the number of terms: ").strip())
5 |         if n <= 0:
6 |             return None
7 |         return n
8 |     except:
9 |         return None
10 |
11 def fibonacci_series(n):
12     if n == 1:

```

Step-04:Explanation

1. The program asks the user to enter a number n.
2. A function is created to generate Fibonacci numbers instead of writing everything in one place.
3. Inside the function, the series starts with 0 and 1.
4. A loop calculates the next numbers by adding the previous two.
5. All the Fibonacci numbers are stored in a list and returned by the function.
6. The main part of the program calls the function and gets the list.
7. Then it prints the numbers in one single line with spaces between them.
8. Using functions makes the code clean, reusable, and easier to improve later.

Task 4: Comparative Analysis – Procedural vs Modular Fibonacci Code.

Feature	Without Functions	With Functions
Code Clarity	Logic is written in one block; harder to read when long	Logic is separated into a named function → easier to understand
Reusability	Cannot reuse Fibonacci logic without rewriting	Can call the function anywhere in program
Debugging Ease	Bugs must be traced in main logic, mixed with other code	Errors isolated in function → easier to test & fix
Suitability for Larger Systems	Poor; not scalable, becomes messy with added features	Good; fits into bigger systems, easier to maintain
Testing	Hard to unit test a part of code independently	Function can be tested separately with multiple inputs
Maintainability	Low; changes affect entire code block	High; changes only in function, no impact on main flow
Performance Impact	No function call overhead (very small benefit)	Minimal overhead but worth it for structure & scaling

Task 5: AI-Generated Iterative vs Recursive Fibonacci Approaches (Different Algorithmic Approaches for Fibonacci Series)

Step-01: Prompt

Generate iterative and recursive Fibonacci code in Python. Take user input n. Keep code clean and optimized. Add explanation on efficiency.

The screenshot shows the Microsoft Visual Studio Code interface with the "AI ASSISTED CODING" extension active. The code editor displays two files: `Fibonacci.py` and `fibonacci_series.py`. The `fibonacci_series.py` file contains the following code:`def get_input():
 return n
except:
 return None

def fibonacci_series(n):
 if n == 1:
 return [0]
 seq = [0, 1]
 for _ in range(n - 2):
 seq.append(seq[-1] + seq[-2])
 return seq

def main():
 n = get_input()
 if n is None:
 return
 series = fibonacci_series(n)
 print(' '.join(map(str, series)))

if __name__ == "__main__":
 main()`

The terminal below shows the output of running the script with 10 terms:`PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING & C:/Users/maddi/AppData/Local/Microsoft/WindowsApps/python3.11.exe
Enter the number of terms: 10
0 1 1 2 3 5 8 13 21 34
PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING>`

Step-02:Code

The screenshot shows the Microsoft Visual Studio Code interface with the "AI ASSISTED CODING" extension active. The code editor displays the `fibonacci_series.py` file from the previous step, now including memoization for the recursive implementation. The code is as follows:`# Recursive Fibonacci (with memoization for efficiency)
def fibonacci_recursive(n, memo=None):
 if memo is None:
 memo = {}
 if n in memo:
 return memo[n]
 if n <= 1:
 memo[n] = n
 return n
 memo[n] = fibonacci_recursive(n-1, memo) + fibonacci_recursive(n-2, memo)
 return memo[n]

def fibonacci_series_recursive(n):
 return [fibonacci_recursive(i) for i in range(n)]

def main():
 n = get_input()
 if n is None:
 return
 print("Choose Fibonacci implementation:")
 print("1. Iterative (efficient)")
 print("2. Recursive (with memoization)")
 choice = input("Enter 1 or 2: ").strip()
 if choice == '1':
 series = fibonacci_series(n)
 print("Iterative Fibonacci series:")
 print(' '.join(map(str, series)))
 print("\nEfficiency explanation:")
 print("Iterative approach runs in O(n) time and uses O(n) space. Recursive with memoization also runs in O(n) time but has higher function call overhead due to recursion stack. Memoization reduces redundant calculations by storing previously computed results in a dictionary 'memo'.")
 else:
 series = fibonacci_series_recursive(n)
 print("Recursive (with memoization) Fibonacci series:")
 print(' '.join(map(str, series)))
 print("\nEfficiency explanation:")
 print("Iterative approach runs in O(n) time and uses O(n) space. Recursive with memoization also runs in O(n) time but has higher function call overhead due to recursion stack. Memoization reduces redundant calculations by storing previously computed results in a dictionary 'memo'.")

if __name__ == "__main__":
 main()`

Step-03:Output

```

```

In 38, Col 46 Spaces: 4 UTF-8 {} Python 3.13.9 (Microsoft Store) 0:0 Go Live

Step-04:Explanation

Iterative Approach

1. The program takes n from the user.
2. It starts Fibonacci with two variables: a = 0, b = 1.
3. A loop runs n times to create the sequence step by step.
4. In each round, it prints a, then updates the values (a becomes b, b becomes a + b).
5. This method is fast, uses very little memory, and works well even for big n.

Efficiency:

- Time: $O(n)$ → runs in a straight line with loop
- Space: $O(1)$ → only 2 variables used

Recursive Approach

1. The program takes n from the user.
2. A recursive function calls itself to find Fibonacci numbers.
3. It breaks the problem into smaller parts: $\text{fib}(n) = \text{fib}(n-1) + \text{fib}(n-2)$.
4. It keeps calling itself until it reaches the base values (0 and 1).
5. This method is slow for large n because it repeats the same work many times.

Efficiency:

- Time: $O(2^n)$ → grows very fast, not good for big n

- Space: $O(n)$ → stack memory is used for every call

Comparison:

Aspect	Iterative	Recursive
Time Complexity	$O(n)$	$O(2^n)$ (very slow due to repeated calls)
Space Complexity	$O(1)$	$O(n)$ (stack memory for calls)
Performance for Large n	Excellent (can handle 10^7+ if needed)	Poor (fib(50) may take seconds/minutes)
Memory Usage	Very low	High because of recursion stack
Scalability	Best for real systems	Not scalable without optimization
Risk	No crash risk	StackOverflow for large n
